On the use of isoparametric elements for BEM modeling of arbitrarily shaped thin wires in electromagnetic compatibility applications

D. Poljak, V. Doric & D. Cavka

University of Split, Croatia

Abstract

The paper deals with the frequency domain Galerkin-Bubnov scheme of the Indirect Boundary Element Method (GB-IBEM) for the solution of the Pocklington integral equations for arbitrary thin wire configurations. The presence of a lossy media is taken into account by using both the reflection coefficient approximation and the rigorous Sommerfeld integral formulation. Some illustrative computational examples related to power line communication systems (PLC) and grounding systems are presented.

Keywords: boundary elements, frequency domain modeling, Pocklington equation, thin wires of arbitrary shape.

1 Introduction

The most rigorous approach to analyze the electromagnetic field coupling to arbitrary configurations of overhead and buried wires, respectively, is related to the use of the antenna theory (the full wave approach) [1, 2]. Such a formulation is usually based on a corresponding set of the Pocklington integral equations [3, 4]. If one deals with the frequency domain formulation the related transient response is evaluated via the Inverse Fourier Transform (IFT). An important feature of the integral equation approach is the use of isoparametric elements for an efficient treatment of curved wires, which is not readily the case with a transmission line approximation [4]. On the other hand, the most serious drawback of the antenna theory is relatively long computational time required for the analysis of complex structures [1, 2].

The excitation of aboveground and belowground wire configurations is of particular interest in electromagnetic compatibility (EMC). The knowledge of
the induced current distribution is a prerequisite to understand the behaviour of related scattered fields, induced voltages and other parameters of the structure. The simplest procedure is to approximate the current distribution along the given wire structure. However, many applications require a more accurate approach related to the solution of a corresponding integral equation [1, 2].

The present paper overviews the analysis methods of electromagnetic field coupling to overhead and belowground wires in the frequency domain by means of the wire antenna model. Furthermore, the Galerkin-Bubnov scheme of the Indirect Boundary Element Method (GB-IBEM) for the solution of Pocklington equations is discussed. Some illustrative computational examples pertaining to overhead wires and grounding systems are given in the paper.

2 Integral equation formulations for arbitrary wire structures

This section outlines the basic principles in the analysis of field coupling to arbitrarily shaped overhead and buried wire configurations via the antenna theory approach. In both cases the formulation features the theory of images thus replacing either upper or lower half space respectively, as depicted in Fig 1.

![Diagram of a wire and its image](image-url)

Figure 1: The wire of an arbitrary shape and its image.
2.1 Overhead wire configurations

The currents $I(s_n')$ induced along multiple curved wires located above a lossy ground are governed by the set of corresponding Pocklington integral equations given by [5]:

$$E_{inc}^w(s_n) = \frac{j}{4\pi\varepsilon_0} \sum_{n=1}^{N_w} \int_0^{l_n} \left[ \kappa^2 \mathbf{\hat{e}}_s \mathbf{\hat{e}}_{s'} - \frac{\partial^2}{\partial s \partial s'} \right] g_{0n}(s_m, s_n') + R_{TM} \left[ \kappa^2 \mathbf{\hat{e}}_s \mathbf{\hat{e}}_{s'} - \frac{\partial^2}{\partial s \partial s'} \right] g_{n}(s_m, s_n') +$$

$$(R_{TE} - R_{TM}) \mathbf{\hat{e}}_s \mathbf{\hat{e}}_p \cdot \left[ k^2 \mathbf{\hat{e}}_p \mathbf{\hat{e}}_{s'} - \frac{\partial^2}{\partial s \partial s'} \right] g_{0n}(s_m, s_n') \right] I(s_n') ds' + Z_{Lm} I(s_m), \quad m = 1, 2, \ldots N_w$$

where $N_w$ is the total number of wires, $I_n(s_n')$ is the unknown current distribution along the $n$-th wire, $\mathbf{\hat{e}}_p$ is the unit vector normal to the incident plane while $g_{0mn}(x,x')$ and $g_{imn}(s,s')$ are the Green functions of the form:

$$g_{0mn}(s_m, s_n') = \frac{e^{-jk R_{1mn}}}{R_{1mn}}, \quad g_{imn}(s_m, s_n') = \frac{e^{-jk R_{2mn}}}{R_{2mn}}$$

where and $R_{1mn}$ and $R_{2mn}$ are distances from the source point and from the corresponding image, respectively to the observation point of interest.

The influence of a lossy half-space is taken into account via the Fresnel plane wave reflection coefficient (RC) for TM and TE polarization, respectively [5]:

$$R_{TM}' = \frac{n \cos \theta' - \sqrt{n^2 - \sin^2 \theta'}}{n \cos \theta' + \sqrt{n^2 - \sin^2 \theta'}}$$

$$R_{TE} = \frac{\cos \theta' - \sqrt{n^2 - \sin^2 \theta'}}{\cos \theta' + \sqrt{n^2 - \sin^2 \theta'}}$$

where $\theta'$ is the angle of incidence and $n$ is given by:

$$n = \frac{\varepsilon_{\text{eff}}}{\varepsilon_0}, \quad \varepsilon_{\text{eff}} = \varepsilon_r \varepsilon_0 - j \frac{\sigma}{\omega}$$

and $\varepsilon_{\text{eff}}$ denotes the complex permittivity of the ground, while $\omega$ is the operating frequency.

Once the currents along the wire array are known, the radiated field components could be evaluated. The total electric field irradiated by configuration of arbitrarily shaped multiple wires is given by [3, 6]:

$$\vec{E} = \sum_{n=1}^{N_w} \left[ \vec{E}_{0n} + R_{TM} \vec{E}_{in} + (R_{TE} - R_{TM}) \left( \vec{E}_{in} \cdot \mathbf{\hat{e}}_p \right) \mathbf{\hat{e}}_p \right]$$

where:

$$\vec{E}_{0n} = \frac{1}{4\pi \varepsilon_0} \left[ k^2 \int_0^{l_n} \left( \mathbf{\hat{e}}_{s_n} I(s_n') g_{0n}(\vec{r}, \vec{r}') ds_n' + \frac{\partial I(s_n')}{\partial s_n'} \nabla g_{0n}(\vec{r}, \vec{r}') ds_n' \right) \right]$$

$$

\text{WIT Transactions on Modelling and Simulation, Vol 53, © 2012 WIT Press}
\text{www.witpress.com, ISSN 1743-3533 (on-line)}
\[
\vec{E}_{in} = \frac{1}{j4\pi\omega e_0} \left[ k_1^2 \int_0^{L_1} \tilde{\varepsilon}_{s_n} \cdot \vec{j}(s') \, C_{in}(\vec{r}, \vec{r}^*) \, d\omega' \right] - \int_0^{L_2} \frac{\partial I(s')}{\partial s_n^*} \nabla C_{in}(\vec{r}, \vec{r}^*) \, ds'
\]

Note that index 0 and 1 is related to the source and image wire, respectively. The total magnetic field can be determined from similar relations [3, 6].

### 2.2 Buried wire configurations

The currents induced along the complex grounding system can be obtained as a solution of the following set of the coupled Pocklington integro-differential equations for \( N_W \) wires of arbitrary shape:

\[
E_{nm}^{\infty}(s_n) = -\frac{1}{j4\pi\omega e_{eff}^{\infty}} \sum_{m=1}^{\infty} \left[ \int_{s_n^2} I(s_n') \cdot \tilde{\varepsilon}_{s_n} \cdot \vec{s}_n^\star \left[ k_0^2 + \nabla \nabla \right] C_{nm}(s_n, s_n') \, ds_n' + \frac{k_0^2 - k_1^2}{k_0^2 + k_1^2} \int_{s_n^2} I(s_n') \cdot \tilde{\varepsilon}_{s_n} \cdot \vec{s}_n^\star \left[ k_1^2 + \nabla \nabla \right] C_{nm}(s_n, s_n') \, ds_n' \right] + \int_{s_n^2} I(s_n') \cdot \tilde{\varepsilon}_{s_n} \cdot \vec{s}_n^\star \cdot G_j(s_n, s_n') \, ds_n',
\]

where \( k_0 \) and \( k_1 \) are propagation constants of air and lossy ground, respectively:

\[
k_0^2 = \omega^2 \mu_0 \varepsilon_0
\]

\[
k_1^2 = \omega^2 \mu_0 \varepsilon_{eff}^{\infty}
\]

while \( g_{0nm} \) and \( g_{nm} \) are the corresponding Green functions [4]. The kernel:

\[
\tilde{G}_j(s, s') = (\tilde{\varepsilon}_{s} \cdot \vec{s}') \cdot (G_{\rho}^R \cdot \tilde{\varepsilon}_{\rho} + G_{\rho}^H \cdot \tilde{\varepsilon}_{\rho} + G_{\phi}^H \cdot \tilde{\varepsilon}_{\phi} + G_{\phi}^R \cdot \tilde{\varepsilon}_{\phi}) + (\tilde{\varepsilon}_{s} \cdot \vec{s}') \cdot (G_{\rho}^R \cdot \tilde{\varepsilon}_{\rho} + G_{\rho}^H \cdot \tilde{\varepsilon}_{\rho} + G_{\phi}^H \cdot \tilde{\varepsilon}_{\phi} + G_{\phi}^R \cdot \tilde{\varepsilon}_{\phi})
\]

consists of the following terms [7]:

\[
G_{\rho}^R = \frac{\partial^2}{\partial \rho \partial z} k_0^2 V^R
\]

\[
G_{\rho}^H = \frac{\rho}{\cos \phi} \left( \frac{\partial^2}{\partial \rho^2} k_0^2 V^R + k_1^2 U^R \right)
\]

\[
G_{\phi}^H = -\sin \phi \left( \frac{1}{\rho} \frac{\partial}{\partial \rho} k_1^2 V^R + k_1^2 U^R \right)
\]

\[
G_{\rho}^H = -j4\pi\omega e_{eff}^{\infty} \cos \phi G_{\rho}^R
\]

Where the Sommerfeld integral terms are:

\[
U^R = \int_0^{\infty} D_1(\lambda) e^{-\gamma_0 |z|} J_0(\lambda \rho) \lambda \, d\lambda, \quad D_1(\lambda) = \frac{2}{\gamma_0 + \gamma_1} - \frac{2k_1^2}{\gamma_1 \left( k_1^2 + k_0^2 \right)}
\]
\[ V^R = \int_0^\infty D_2(\lambda)e^{-\gamma_1 l\lambda}f_0(\lambda\rho)\lambda d\lambda , D_2(\lambda) = \frac{2}{k_1^2\gamma_0 + k_0^2\gamma_1} - \frac{2}{\gamma_1(k_1^2 + k_0^2)} \]  

(19)

where

\[ \gamma_0 = \sqrt{\lambda^2 - k_0^2} ; \quad \gamma_1 = \sqrt{\lambda^2 - k_1^2} \]  

(20)

Integrals (18) and (19) are computed numerically [4].

3 Numerical solution of Pocklington type equations

The set of Pocklington integro-differential equations (1) and (9) is handled via the (GB-IBEM) featuring isoparametric elements.

The unknown current \( I_n^e(\zeta) \) along the \( n \)-th wire segment is expressed by the sum of a finite number of linearly independent basis functions \( f_{ni} \), with unknown complex coefficients \( I_{ni} \):

\[ I_n^e(\zeta) = \sum_{i=1}^{N_n} I_{ni} f_{ni}(\zeta) = \{f\}_n^T \{I\}_n \]  

(21)

where \( n \) is the number of local nodes per the element.

3.1 BEM procedures for overhead wires

Applying the weighted residual approach and performing the Galerkin-Bubnov procedure the set of coupled integro-differential equations (1) is transformed into the following matrix equation [3, 6]:

\[ \sum_{n=1}^{N_w} \sum_{i=1}^{N_n} [Z]_{ji} \{I\}_i^e = \{V\}_j^e , m = 1, 2, ..., N_w ; \quad j = 1, 2, ..., N_m \]  

(22)

where \( N_w \) is the total number of wires, while \( N_m \) and \( N_n \) denotes the number of elements on the \( m \)-th and the \( n \)-th wire, respectively.

The mutual impedance matrix is given by [3, 6]:

\[ [Z]_{ji} = \int_{-1}^{1} \int_{-1}^{1} \{D\}_j \{D\}_i^T \gamma_{0\text{mun}}(s_n,s_m) \frac{ds_n}{d\xi} \frac{ds_m}{d\zeta} \frac{ds_n}{d\zeta} \frac{ds_m}{d\xi} + k_1^2 \epsilon_\zeta \epsilon_{\zeta} \epsilon_n \int_{-1}^{1} \{f\}_j \{f\}_i^T \gamma_{0\text{mun}}(s_n,s_m) \frac{ds_n}{d\xi} \frac{ds_m}{d\zeta} \frac{ds_n}{d\zeta} \frac{ds_m}{d\xi} - \\
- R_{TM} \int_{-1}^{1} \int_{-1}^{1} \{D\}_j \{D\}_i^T \gamma_{0\text{mun}}(s_n,s_m) \frac{ds_n}{d\xi} \frac{ds_m}{d\zeta} \frac{ds_n}{d\zeta} \frac{ds_m}{d\xi} + R_{TM} k_1^2 \epsilon_\zeta \epsilon_{\zeta} \epsilon_n \int_{-1}^{1} \{f\}_j \{f\}_i^T \gamma_{0\text{mun}}(s_n,s_m) \frac{ds_n}{d\xi} \frac{ds_m}{d\zeta} \frac{ds_n}{d\zeta} \frac{ds_m}{d\xi} \\
+ \frac{j}{4\pi\epsilon_0} \int_{-1}^{1} \int_{-1}^{1} \{Z\}_j \{f\}_i^T \frac{ds_n}{d\zeta} \frac{ds_m}{d\xi} \]  

(23)

while the voltage vector is [3, 6]:

\[ \{V\}_j^e = - j 4\pi \epsilon_0 \int_{-1}^{1} \{E\}_n^{\text{exc}}(s_n) \{f\}_j \frac{ds_n}{d\zeta} \frac{ds_n}{d\xi} \]  

(24)
Matrices \( \{ f \} \) and \( \{ f' \} \) contain the shape functions while \( \{ D \} \) and \( \{ D' \} \) contain their derivatives. Once the current distribution is obtained, the radiated field can be obtained applying the similar BEM formalism [3, 6]. Thus, the total field is given by:

\[
\vec{E} = \sum_{k=1}^{N} \left( \vec{E}_{sk}^e + R_{TM} \vec{E}_{rk}^e + \left( R_{TE} - R_{TM} \right) \left( \vec{E}_{rk}^e \cdot \vec{e}_{p} \right) \vec{e}_{p} \right)
\]

where:

\[
\vec{E}_{sk}^e = \frac{1}{j 4 \pi \omega c_0} \sum_{i=1}^{n} \left[ k^2 \left( I_{ik \alpha} R_{k} f(\xi) g_{0k}(\vec{r}, \vec{r}') \frac{ds}{d \xi} \right) d \xi + \int \left( I_{ik \alpha} \frac{\partial f(\xi)}{\partial \xi} \nabla g_{0k}(\vec{r}, \vec{r}') \frac{ds}{d \xi} \right) d \xi \right]
\]

\[
\vec{E}_{rk}^e = \frac{1}{j 4 \pi \omega c_0} \sum_{i=1}^{n} \left[ k^2 \left( I_{ik \alpha} R_{k} f(\xi) g_{sk}(\vec{r}, \vec{r}') \frac{ds}{d \xi} \right) d \xi - \int \left( I_{ik \alpha} \frac{\partial f(\xi)}{\partial \xi} \nabla g_{sk}(\vec{r}, \vec{r}') \frac{ds}{d \xi} \right) d \xi \right]
\]

Numerical procedures for the computation of radiated magnetic field are presented in [3, 6].

### 3.2 BEM procedure for Pocklington equation for buried wires

Applying the weighted residual approach featuring the Galerkin-Bubnov procedure the set of Pocklington equations (9) is transformed into a system of algebraic equations:

\[
\sum_{m=1}^{N} \sum_{j=1}^{N_{m}} \left[ Z_{ji} \right]_{m} \{ I_{m} \}_{i} = 0, \quad m = 1, 2, ..., N_{m}, \quad j = 1, 2, ..., N_{m}
\]

where the mutual impedance matrix is of the form:

\[
[Z]_{ji} = -\int \left( \int \{ D \} \{ D' \} \{ \gamma_{0m}(s_{m},s') \} \frac{ds}{d q} d q' \frac{ds}{d q} d q' + k^2 \gamma_{sk} \frac{ds}{d q} d q' \frac{ds}{d q} d q' \right) + \int \left( \int \{ D \} \{ D' \} \{ \gamma_{sk}(s_{k},s') \} \frac{ds}{d q} d q' \frac{ds}{d q} d q' \right) + \int \left( \int \{ D \} \{ D' \} \{ \gamma_{sk}(s_{k},s') \} \frac{ds}{d q} d q' \frac{ds}{d q} d q' \right)
\]

Note that the current source excitation \( I_{g} \) is taken into account as a forced boundary condition at a certain node \( i \) of the grounding system [4, 7]:

\[
I_{g} = I_{g}
\]

The treatment of wire junctions is related to the Kirchhoff’s current law forcing the continuity of currents and charges at the junction [4]. The input impedance of the grounding system is given by:

\[
Z_{m} = -\frac{1}{I_{g}} \int \vec{E} d \vec{s}
\]

where the line integral represents the driving point voltage.
The desired frequency response of the grounding system is obtained by multiplying the input impedance spectrum with the excitation spectrum. The transient response is calculated by means of the IFFT.

4 Computational examples

The computational examples are related to a simple power line communications system and a realistic grounding system for wind turbines.

4.1 PLC system analysis

PLC technology provides users with communication means via the existing distributed power line network or electrical installations. Electromagnetic interference (EMI) is one of the principal drawbacks of this technology as overhead power lines radiate at PLC frequencies (1 MHz to 30 MHz) [6].

Fig 2 shows the geometry of a simple PLC system. The conductors are modelled as thin wires excited by the voltage generator $V_g$ at one end, and terminated by the load impedance $Z_L$ at the other end.

![Figure 2: A simple PLC system.](image)

The wire radius is $a=6.35\text{mm}$, and the distance between poles is $L=200\text{m}$. The conductors are suspended on the poles at height $h=10\text{m}$ and $11\text{m}$, respectively, while the maximal conductor sag is $s=2\text{m}$. The maximal conductor sag is $s=2\text{m}$. The lossy ground parameters are $\varepsilon_r=13$ and $\sigma=0.005\text{S/m}$.

The impressed power is $2.5\mu\text{W}$ (minimum power required for the PLC system operation) and operating frequency is $14\text{MHz}$. The value of the terminating load $Z_L$ is $500\Omega$.

Fig 3 shows the radiated electric field, at the distance of $30\text{m}$ from the wires and $10\text{m}$ above a lossy ground.
Installation of entire lightning protection system for wind turbines has become of particular importance [8, 9]. Namely, wind turbines are quite often struck by lightning due to their special shape, complex construction and the fact that they are usually placed in isolated locations, mainly at higher altitudes. Therefore, low-impedance grounding system is a major prerequisite for a satisfactory protection of wind turbines from lightning strikes.

Fig 4 shows an arbitrary wind turbine grounding system subjected to a lighting strike. Note that the influence of WT itself (tower, blades etc.) is neglected.
Fig 5 shows a typical configuration of grounding systems for wind turbines. The grounding system consists of a square of galvanized steel flanges (Fe/Zn 30x3.5mm – gray line in fig 2) at the 2m depth, two copper ring wires (Cu 70 mm$^2$ - black line in fig 2) at different levels (smaller one of 3.25m radius at 5cm depth and the larger with 6.8m radius buried at 55cm depth) and additional four copper wires. All parts of the grounding system are connected by aluminothermy welding.

The grounding system is placed in a homogenous soil of relatively high specific resistance of $\rho=1200\Omega/m$ and the relative dielectric constant $\varepsilon_r=9$.

The lightning current is expressed by the double exponential function:

$$i(t) = I_0 \left( e^{-\alpha t} - e^{-\beta t} \right)$$

with: $I_0=1.1043A$, $\alpha=0.07924\cdot10^6s^{-1}$, $\beta=0.07924\cdot10^6s^{-1}$.

Fig 6 shows the transient response of the grounding system. Dashed line represents a ten times higher input current waveform for the comparison purpose.
It can be seen that the maximal value of voltage is about 37 V and it is reached slightly after current peak value. Transient impedance continuously increases from zero to maximal value of 40 Ω.

5 Closure

The paper deals with the frequency domain Galerkin-Bubnov scheme of the Indirect Boundary Element Method (GB-IBEM) for the solution of Pocklington integral equations for an efficient treatment of arbitrarily shaped wires featuring the use of isoparametric elements.

The presence of a dissipative half-space is taken into account by using both reflection coefficient approximation for overhead wires and rigorous Sommerfeld integral formulation for buried conductors, respectively.

Some illustrative numerical results pertaining to PLC systems and grounding systems are given in the paper.
